prime student Coll

This second edition of *D* consistent coverage of b concepts using C langua introduction of different d

- Homework: 35%
- Midterm: 35%
- Final: 40%

Data Type

- The programming language ‘C’ was developed in the early 1970s by Dennis Ritchie at Bell Laboratories
 - C was initially developed for writing system software
- Data type determines the set of values that a data item can take and the operations that can be performed on the item

Data Type	Size in Bytes	Range	Use
char	1	-128 to 127	To store characters
int	2	-32768 to 32767	To store integer numbers
float	4	3.4E-38 to 3.4E+38	To store floating point numbers
double	8	1.7E-308 to 1.7E+308	To store big floating point numbers

- Note that C does not provide any data type for storing text
 - Text is made up of individual characters
 - “char” is supposed to store characters not numbers?
 - ✓ In the memory, characters are stored in their ASCII codes
 - ✓ ‘A’ has the ASCII code of 65

ASCII Codes

- In C language
 - ‘5’ == int 53
 - ‘5’-’0’==int 53 – int 48 == int 5
 - If char c = ‘B’+32, then c==‘b’

ASCII TABLE

Decimal	Hex	Char	Decimal	Hex	Char	Decimal	Hex	Char	Decimal	Hex	Char
0	0	[NULL]	32	20	[SPACE]	64	40	@	96	60	`
1	1	[START OF HEADING]	33	21	!	65	41	A	97	61	a
2	2	[START OF TEXT]	34	22	"	66	42	B	98	62	b
3	3	[END OF TEXT]	35	23	#	67	43	C	99	63	c
4	4	[END OF TRANSMISSION]	36	24	\$	68	44	D	100	64	d
5	5	[ENQUIRY]	37	25	%	69	45	E	101	65	e

30	1E	[RECORD SEPARATOR]	62	3E	>	94	5E	^	126	7E	~
31	1F	[UNIT SEPARATOR]	63	3F	?	95	5F	_	127	7F	[DEL]

Program

- A **program** contains one or more functions, where a function is defined as a group of statements that perform a well-defined task
 - A program should undoubtedly give correct results, but along with that it should also run efficiently
- The definition of a good program is
 - runs correctly
 - easy to read and understand
 - easy to debug
 - easy to modify

```
main()
{
    Statement 1;
    Statement 2;
    .....
    .....
    Statement N;
}
Function1()
{
    Statement 1;
    Statement 2;
    .....
    .....
    Statement N;
}
Function2()
{
    Statement 1;
    Statement 2;
    .....
    .....
    Statement N;
}
.....
.....
FunctionN()
{
    Statement 1;
    Statement 2;
    .....
    .....
    Statement N;
}
```

Algorithm.

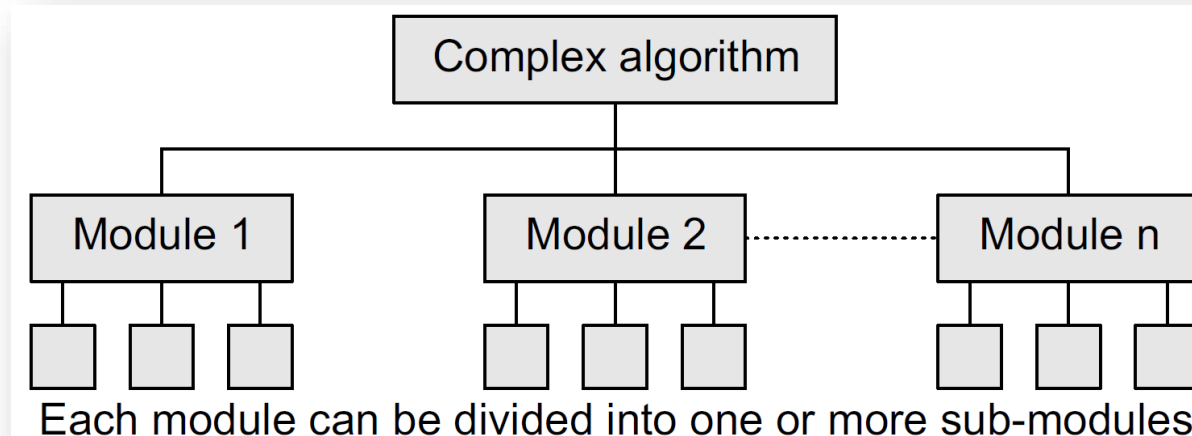

- The typical definition of algorithm is “a formally defined procedure for performing some calculation”
 - In general terms, an algorithm provides a blueprint to write a program to solve a particular problem
 - A program **does not** have to satisfy **the fourth condition**

Definition: An *algorithm* is a finite set of instructions that, if followed, accomplishes a particular task. In addition, all algorithms must satisfy the following criteria:

- (1) **Input.** Zero or more quantities are externally supplied.
- (2) **Output.** At least one quantity is produced.
- (3) **Definiteness.** Each instruction is clear and unambiguous. (明確性)
- (4) **Finiteness.** If we trace out the instructions of an algorithm, then for all cases, the algorithm terminates after a finite number of steps. (有限性)
- (5) **Effectiveness.** Every instruction must be basic enough to be carried out, in principle, by a person using only pencil and paper. It is not enough that each operation be definite as in (3); it also must be feasible. □ (有效性:明確且可行)

Algorithm..

- A complex algorithm is often divided into smaller units called modules
 - This process of dividing an algorithm into modules is called modularization
- The key advantages of modularization are as follows:
 - It makes the complex algorithm simpler to design and implement
 - Each module can be designed independently

Algorithm & Program

Algorithms + Data Structures = Programs (Prentice-Hall Series in Automatic Computation)

Function

- Let us analyze the reasons why segmenting a program (algorithm) into manageable chunks is an important aspect of programming
 - Dividing the program into separate well-defined functions facilitates each function to be written and tested separately
 - Understanding, coding, and testing multiple separate functions is easier than doing the same for one big function
 - Maintaining a huge program will be a difficult task
 - When a big program is broken into comparatively smaller functions, then different programmers working on that project can divide the workload by writing different functions

Recursive Function.

- The recursion mechanisms are extremely powerful, because they often can express a complex process very clearly
- Recursive functions can be categorized into three classes
 - Direct Recursion
 - The function may call itself before it is done
 - Indirect Recursion
 - The function may call other functions that again invoke the calling function
 - Tail Recursion
 - The function may call itself at the end of the function
 - A special case of direct recursion

Recursive Function..

Direct Recursion

```
1 function A()  
2 ▼ {  
3     ...  
4  
5     A() ;  
6  
7     ...  
8 }  
9
```

Indirect Recursion

```
1 function A()  
2 {  
3     ...  
4  
5     B() ;  
6  
7     ...  
8 }  
9  
10 function B()  
11 {  
12     ...  
13  
14     A() ;  
15  
16     ...  
17 }
```

calling cycle

Tail Recursion

```
1 function A()  
2 ▼ {  
3     ...  
4  
5     A() ;  
6 }
```

Recursive Function...

- Let's make a comparison

Recursion	Non-Recursion
Codes are more compact	Codes are complicated
Easy to understand	Hard to read
Time-consuming	Time-saving

Examples – 1

- Please write down a recursive program to do factorial

$$0! = 1$$

$$1! = 1$$

$$2! = 1 \times 2$$

$$3! = 1 \times 2 \times 3$$

$$n! = 1 \times 2 \times 3 \times \cdots \times n$$

```
1 int factorial( int a )
2 {
3     if( a == 0 )
4         return 1 ;
5     else
6         return factorial(a-1)*a ;
7 }
```

Examples – 2.

- Please (1) write a recursive program, *Fib(int a)*, to calculate the Fibonacci number; (2) how many function calls do you need when we want to calculate *Fib(5)*?

Fibonacci number

From Wikipedia, the free encyclopedia

In [mathematics](#), the **Fibonacci numbers** are the numbers in the following [integer sequence](#), called the **Fibonacci sequence**, and characterized by the fact that every number after the first two is the sum of the two preceding ones:^{[1][2]}

1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, ...

Often, especially in modern usage, the sequence is extended by one more initial term:

0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, ...^[3]

By definition, the first two numbers in the Fibonacci sequence are either 1 and 1, or 0 and 1, depending on the chosen starting point of the sequence, and each subsequent number is the sum of the previous two.

The sequence F_n of Fibonacci numbers is defined by the [recurrence relation](#):

$$F_n = F_{n-1} + F_{n-2},$$

with [seed values](#)^{[1][2]}

$$F_1 = 1, F_2 = 1$$

or^[5]

$$F_0 = 0, F_1 = 1.$$

Examples – 2..

- Please write a recursive program, *Fib(int a)*, to calculate the Fibonacci number; (2) how many function calls do you need to do when we want to calculate *Fib(5)*?

$$Fib(a) = \begin{cases} 0, & \text{if } a = 0 \\ 1, & \text{if } a = 1 \\ Fib(a-1) + Fib(a-2), & \text{otherwise} \end{cases}$$

```
1  int Fib( int a )
2  {
3      if( a == 0 )
4          return 0 ;
5      else if( a == 1 )
6          return 1 ;
7      else
8          return Fib(a-1)+Fib(a-2) ;
9  }
```

Examples – 2...

- Please (1) write a recursive program, *Fib(int a)*, to calculate the Fibonacci number; (2) how many function calls do you need to do when we want to calculate *Fib(5)*?

```
1 int Fib( int a )
2 {
3     if( a == 0 )
4         return 0 ;
5     else if( a == 1 )
6         return 1 ;
7     else
8         return Fib(a-1)+Fib(a-2) ;
9 }
```

Examples – 3.

- Given an Ackerman's function $A(m, n)$, please calculate $A(1, 2)$.

$$A(m, n) = \begin{cases} n + 1, & \text{if } m = 0 \\ A(m - 1, 1), & \text{if } n = 0 \\ A(m - 1, A(m, n - 1)), & \text{otherwise} \end{cases}$$

$$A(1, 2) = A(0, A(1, 1))$$

$$A(1, 1) = A(0, A(1, 0))$$

$$A(1, 0) = A(0, 1)$$

$$A(0, 1) = 2$$

Examples – 3..

- Given an Ackerman's function $A(m, n)$, please calculate $A(1, 2)$.

$$A(m, n) = \begin{cases} n + 1, & \text{if } m = 0 \\ A(m - 1, 1), & \text{if } n = 0 \\ A(m - 1, A(m, n - 1)), & \text{otherwise} \end{cases}$$

$$A(1, 2) = A(0, A(1, 1)) = A(0, 3) = 4$$

$$A(1, 1) = A(0, A(1, 0)) = A(0, 2) = 3$$

$$A(1, 0) = A(0, 1) = 2$$

$$A(0, 1) = 2$$
